

Basic Programming assignment 21

1. Write a function that takes a list and a number as arguments. Add the number to the end of the list, then remove the first element of the list. The function should then return the updated list.

Examples:

`next_in_line([5, 6, 7, 8, 9], 1) → [6, 7, 8, 9, 1]`

`next_in_line([7, 6, 3, 23, 17], 10) → [6, 3, 23, 17, 10]`

`next_in_line([1, 10, 20, 42], 6) → [10, 20, 42, 6]`

`next_in_line([], 6) → "No list has been selected"`

```
In [1]: def next_in_line(in_list, in_num):
        if len(in_list) > 1:
            in_list.append(in_num)
            in_list.remove(in_list[0])
            print(f'Output → {in_list}')
        else:
            print('No list has been selected')

next_in_line([5, 6, 7, 8, 9], 1)
next_in_line([7, 6, 3, 23, 17], 10)
next_in_line([1, 10, 20, 42], 6)
next_in_line([], 6)
```

Output → [6, 7, 8, 9, 1]
Output → [6, 3, 23, 17, 10]
Output → [10, 20, 42, 6]
No list has been selected

2. Create the function that takes a list of dictionaries and returns the sum of people's budgets.

Examples: `get_budgets([{"name": "John", "age": 21, "budget": 23000}, {"name": "Steve", "age": 32, "budget": 40000}, {"name": "Martin", "age": 16, "budget": 2700}]) → 65700`

`get_budgets([{"name": "John", "age": 21, "budget": 29000}, {"name": "Steve", "age": 32, "budget": 32000}, {"name": "Martin", "age": 16, "budget": 1600}]) → 62600`

```
In [2]: def get_budgets(in_dict):
        sum = 0
        for ele in in_dict:
            sum += ele["budget"]
            print(f'Output → {sum}')

get_budgets([
    {"name": "John", "age": 21, "budget": 23000},
    {"name": "Steve", "age": 32, "budget": 40000},
    {"name": "Martin", "age": 16, "budget": 2700}
])

get_budgets([
    {"name": "John", "age": 21, "budget": 29000},
    {"name": "Steve", "age": 32, "budget": 32000},
    {"name": "Martin", "age": 16, "budget": 1600}
])
```

Output → 65700
Output → 62600

3. Create a function that takes a string and returns a string with its letters in alphabetical order.

Examples:

`alphabet_soup("hello") → "ehllo"`

`alphabet_soup("edabit") → "abdeit"`

`alphabet_soup("hacker") → "acehkr"`

`alphabet_soup("geek") → "eegk"`

`alphabet_soup("javascript") → "aacijprstv"`

```
In [3]: def alphabet_soup(in_string):
        out_string = ''.join(sorted(in_string))
        print(f'{in_string} → {out_string}')
```

```

alphabet_soup("hello")
alphabet_soup("edabit")
alphabet_soup("hacker")
alphabet_soup("geek")
alphabet_soup("javascript")

```

```

hello → ehlllo
edabit → abdeit
hacker → acehkr
geek → eegk
javascript → aacijprstv

```

4. What will be the value of your investment at the end of the 10 year period?

Create a function that accepts the principal p , the term in years t , the interest rate r , and the number of compounding periods per year n . The function returns the value at the end of term rounded to the nearest cent.

For the example above:

`compound_interest(10000, 10, 0.06, 12)` → 18193.97

Note that the interest rate is given as a decimal and $n=12$ because with monthly compounding there are 12 periods per year. Compounding can also be done annually, quarterly, weekly, or daily.

Examples:

`compound_interest(100, 1, 0.05, 1)` → 105.0

`compound_interest(3500, 15, 0.1, 4)` → 15399.26

`compound_interest(100000, 20, 0.15, 365)` → 2007316.26

```

In [4]: def compound_interest(principal, years, roi, cp):
        ci = principal * (1 + (roi / cp)) ** (cp * years)
        print(f'Output → {ci:.2f}')

        compound_interest(100, 1, 0.05, 1)
        compound_interest(3500, 15, 0.1, 4)
        compound_interest(100000, 20, 0.15, 365)

```

```

Output → 105.00
Output → 15399.26
Output → 2007316.26

```

5. Write a function that takes a list of elements and returns only the integers.

Examples:

`return_only_integer([9, 2, "space", "car", "lion", 16])` → [9, 2, 16]

`return_only_integer(["hello", 81, "basketball", 123, "fox"])` → [81, 123]

`return_only_integer([10, "121", 56, 20, "car", 3, "lion"])` → [10, 56, 20, 3]

`return_only_integer(["String", True, 3.3, 1])` → [1]

```

In [5]: def return_only_integer(in_list):
        out_list = []
        for ele in in_list:
            if type(ele) == int:
                out_list.append(ele)
        print(f'{in_list} → {out_list}')

        return_only_integer([9, 2, "space", "car", "lion", 16])
        return_only_integer(["hello", 81, "basketball", 123, "fox"])
        return_only_integer([10, "121", 56, 20, "car", 3, "lion"])
        return_only_integer(["String", True, 3.3, 1])

```

```

[9, 2, 'space', 'car', 'lion', 16] → [9, 2, 16]
['hello', 81, 'basketball', 123, 'fox'] → [81, 123]
[10, '121', 56, 20, 'car', 3, 'lion'] → [10, 56, 20, 3]
['String', True, 3.3, 1] → [1]

```
