

Basic Programming assignment 18

1. Create a function that takes a list of non-negative integers and strings and return a new list without the strings ?

Examples:

`filter_list([1, 2, "a", "b"]) → [1, 2]`

`filter_list([1, "a", "b", 0, 15]) → [1, 0, 15]`

`filter_list([1, 2, "aasf", "1", "123", 123]) → [1, 2, 123]`

```
In [1]: def filter_list(list):
        out_string = []
        for ele in list:
            if type(ele) == int and ele >= 0:
                out_string.append(ele)
        return out_string

print(f'→ {filter_list([1, 2, "a", "b"])}')
print(f'→ {filter_list([1, "a", "b", 0, 15])}')
print(f'→ {filter_list([1, 2, "aasf", "1", "123", 123])}')
```

→ [1, 2]
→ [1, 0, 15]
→ [1, 2, 123]

2. The "Reverser" takes a string as input and returns that string in reverse order, with the opposite case ?

Examples:

`reverse("Hello World") → "DLROw OLLEh"`

`reverse("ReVeRsE") → "eSrEvEr"`

`reverse("Radar") → "RADAr"`

```
In [2]: def reverse(in_string):
        print(f'{in_string} → {in_string[::-1].swapcase()}')

reverse('Hello World')
reverse("ReVeRsE")
reverse("Radar")
```

Hello World → DLROw OLLEh
ReVeRsE → eSrEvEr
Radar → RADAr

3. You can assign variables from lists like this:

```
lst = [1, 2, 3, 4, 5, 6]
first = lst[0]
middle = lst[1:-1]
last = lst[-1]
print(first) → outputs 1
print(middle) → outputs [2, 3, 4, 5]
print(last) → outputs 6
```

With Python 3, you can assign variables from lists in a much more succinct way. Create variables `first`, `middle` and `last` from the given list using destructuring assignment

(check the Resources tab for some examples), where:

`first` → 1
`middle` → [2, 3, 4, 5]
`last` → 6

Your task is to unpack the list `writeyourcodehere` into three variables, being `first`, `middle`, and `last`, with `middle` being everything in between the first and last element. Then print all three variables.

```
In [3]: first, *middle, last = [1,2,3,4,5,6]
        print(f'first → {first}')
        print(f'middle → {middle}')
        print(f'last → {last}')
```

```
first → 1
middle → [2, 3, 4, 5]
last → 6
```

4. Write a function that calculates the factorial of a number recursively.

Examples:

factorial(5) → 120

factorial(3) → 6

factorial(1) → 1

factorial(0) → 1

```
In [4]: def factorial(n):
        if n==0:
            return 1
        return n * factorial(n-1)

print(f'factorial(5) → {factorial(5)}')
print(f'factorial(3) → {factorial(3)}')
print(f'factorial(1) → {factorial(1)}')
print(f'factorial(0) → {factorial(0)}')

factorial(5) → 120
factorial(3) → 6
factorial(1) → 1
factorial(0) → 1
```

5. Write a function that moves all elements of one type to the end of the list.

Examples:

move_to_end([1, 3, 2, 4, 4, 1], 1) → [3, 2, 4, 4, 1, 1]

Move all the 1s to the end of the array.

move_to_end([7, 8, 9, 1, 2, 3, 4], 9) → [7, 8, 1, 2, 3, 4, 9]

move_to_end(["a", "a", "a", "b"], "a") → ["b", "a", "a", "a"]

```
In [5]: def move_to_end(list,num):
        first_end = []
        second_end = []
        for ele in list:
            if ele == num:
                second_end.append(ele)
            else:
                first_end.append(ele)
        first_end.extend(second_end)
        return first_end

print(f'move_to_end([1, 3, 2, 4, 4, 1], 1) → {move_to_end([1, 3, 2, 4, 4, 1], 1)}')
print(f'move_to_end([7, 8, 9, 1, 2, 3, 4], 9) → {move_to_end([7, 8, 9, 1, 2, 3, 4], 9)}')
print(f'move_to_end(["a", "a", "a", "b"], "a") → {move_to_end(["a", "a", "a", "b"], "a")}')

move_to_end([1, 3, 2, 4, 4, 1], 1) → [3, 2, 4, 4, 1, 1]
move_to_end([7, 8, 9, 1, 2, 3, 4], 9) → [7, 8, 1, 2, 3, 4, 9]
move_to_end(["a", "a", "a", "b"], "a") → ['b', 'a', 'a', 'a']
```
