## Python Advanced Assignment 12

#### Does assigning a value to a string's indexed character violate Python's string immutability?

Ans: String's indexed character cannot to be assigned a New value , as Strings are immutable. Example:

name = "Reinforcement"

print(id(name)) #73472

name[0] = "V" # Raises TypeError

# 2. Does using the += operator to concatenate strings violate Python's string immutability? Why or why not?

Ans: += operator is used to concatenate strings, it does not violate Python's string immutability Property. Because doing so new creates a new association with data and variable. E.g. str\_1="a" and str\_1+="b". effect of this statements to create string ab and reassign it to variable str 1, any string data is not actually modified.

```
In [1]: str_1 = 'a'
    print(id(str_1))
    str_1 += 'b'
    print(id(str_1)) # Does not Modify existing string, Creates a New String Object

2122154235312
2122234490608
```

### 3. In Python, how many different ways are there to index a character?

Ans: A Character in string can be indexed using string name followed by index number of character in square bracket. Positive Indexing i.e. first index is 0 an so on, or Negative Indexing i.e. last letter is -1 and so on can be used to index a character

```
In [2]: in_string = "iNeuron Full Stack Data Science"
    print(in_string[9],in_string[10],in_string[2]) # Positive Indexing
    print(in_string[-1],in_string[-5],in_string[-2]) # Negative Indexing

u l e
    e i c
```

## 4. What is the relationship between indexing and slicing?

Ans: We can access elements of sequence datatypes by using slicing and indexing. Indexing is used to obtaining individual element while slicing for sequence of elements.

```
In [3]: in_string = "iNeuron Full Stack Data Science"
    print(in_string[1],in_string[3],in_string[5]) # Indexing
    print(in_string[1:15]) # Slicing
N u o
```

Neuron Full St

# 5. What is an indexed character's exact data type? What is the data form of a slicing-generated substring?

Ans: Indexed characters and sliced substrings have datatype String.

```
in_string = "iNeuron Full Stack Data Science"
print(type(in_string[3])) # Indexing -> str
print(type(in_string[1:10])) # Indexing -> str

<class 'str'>
<class 'str'>
```

## 6. What is the relationship between string and character "types" in Python?

Ans: Object that contains sequence of character datatypes are called String.

7. Identify at least two operators & one method that allow you to combine one or

### more smaller strings to create a larger string?

Ans: +, += and \* allow to combine one or more smaller strings to create a larger string. <string>.join(<sep>) method joins element of iterable type like list and tuple to get a combined string.

```
In [5]: in_string = 'iNeuron '
    in_string += 'Full Stack Data Science'
    print(in_string + ' FSDS')
    print('FSDS '*3)
    print(" ".join(['I','N','E','U','R','0','N'])) # List Iterable
    print(" ".join(('I','N','E','U','R','0','N')).lower()) # Tuple Iterable

iNeuron Full Stack Data Science FSDS
    FSDS FSDS
    I N E U R O N
    i n e u r o n
```

# 8. What is the benefit of first checking the target string with in or not in before using the index method to find a substring?

Ans: Checking the target string with in or not Operators before using the index method to find a substring just helps confirming availability of substring and thus avoid raising of **ValueError**.

Example:

in\_string = "ineuron"
in\_string.index('x') # Raises ValueError
in\_string.index('u') # 3

# 9. Which operators and built-in string methods produce simple Boolean (true/false) results?

Ans: The String Operators and built-in methods to Produce Simple Boolean (True/False) Results are:

- in
- not
- <string>.isalpha()
- <string> .isalnum()
- <string> .isdecimal()
- <string> .isdigit()
- <string> .islower()
- <string> .isnumeric()
- <string> .isprintable()
- <string> .isspace()
- <string> .istitle()
